Follow-up analysis: where does Amsterdam need new Cooling Places?

Amsterdam now has almost 80 Cooling Places. The current dashboard already shows basic network coverage, such as the share of residents living within 500 metres or 1 kilometre of a Cooling Place.

The next step is to make the dashboard more useful for decision-making. We want to understand not only *where coverage is missing*, but also *where the need is highest*.

Main question

Where should Amsterdam prioritise new Cooling Places, based on the combination of limited coverage, heat stress, vulnerability and expected demand?

Focus of the analysis

Nojus will build on the existing dashboard and explore:

- which areas are still underserved by the current Cooling Places network;
- where limited coverage overlaps with heat stress and vulnerable residents, such as older people, residents with low socioeconomic status or people with limited mobility;
- how many vulnerable residents live in underserved areas;
- whether some neighbourhoods may need more than one Cooling Place because the potential demand is high;
- how many residents, and specifically vulnerable residents, each existing Cooling Place potentially serves;
- which areas may be over-reliant on only one nearby Cooling Place;
- which existing buildings or facilities in priority areas could be promising as additional Cooling Places;
- which extra indicators, maps or filters would make the dashboard more useful for GGD, policymakers and district teams.

Possible outputs

- A priority map showing where limited coverage, heat stress and vulnerability overlap.
- An estimate of potential demand per area and per Cooling Place.

- A shortlist of neighbourhoods (& maybe even streets) where additional Cooling Places are most needed.
- A first scan of promising locations in those priority areas.

The aim is to move from a basic coverage map towards a more targeted and equitable expansion strategy for Amsterdam's Cooling Places network.

People to involve

Several colleagues can provide relevant data, methodological input and inspiration:

- **Floris Harten** and **Clara Keuken** from the Ingenieursbureau, especially on spatial analysis, GIS, heat maps and the link with outdoor cooling.
- Floris and Clara are also supervising a **trainee** who is working on a similar analysis for outdoor cooling spots. It would be useful to align both analyses, so that indoor Cooling Places and outdoor cooling locations can eventually be understood as one connected cooling network.
- **Frans Wijkhuizen,** data specialist from the Climate Adaptation programme, especially on available municipal datasets and data quality.
- **Jelte Hermans** from the Climate Adaptation programme, especially on the policy context, prioritisation and how the analysis can support decision-making.

Data to explore

Nojus can start with the datasets already used in the current Cooling Places dashboard, and then explore which additional data could help estimate need and potential demand more accurately. Relevant datasets may include:

- current Cooling Places locations;
- population data per neighbourhood or grid cell;
- Heatriskmap and heat stress maps
- age data, especially older residents;
- indicators for socioeconomic vulnerability;
- data on social vulnerability or health-related vulnerability;
- walking distance or street network data, instead of only straight-line distance;
- locations of public or semi-public buildings, such as libraries, community centres, churches, museums, hotels and social facilities;
